

SUGGESTED APPROACH TO SELECTING THE ABSTRACTS

- 1. Use the score!! This is the most fair and just way for the presenters
 - 2. Can you trust the score?
 - How many reviewers?
 - Look at the standard deviation?
 - We tried to provide more specific instructions this year and we want to do more of that next year. What do you think?
 - 3. Gestalt or common topics (for those with more than one platform sessions)
 - 4. Begin grouping
 - 5. Decide platform (8 abstracts) or poster symposium (8-12 abstracts)
 - 6. Assign titles that reflect the general topic of the session unless there is only one session (can also use Roman Numerals)
 - 7. Assign moderators
-

TITLE: Chromatin Landscapes of the Vascular Endothelium in Systemic Lupus

ROLE TYPE: Abstract

AUTHORS/INSTITUTIONS: J. Hui-Yuen, Cohen Children's Medical Center, New Hyde Park, New York, UNITED STATES; J.N. Jarvis, Pediatrics, University at Buffalo, Buffalo, New York, UNITED STATES;

CURRENT CATEGORY: Genomics/Epigenomics

First author trainee?: No, Not a Trainee

KEYWORDS: pediatric lupus, genomics, vascular endothelium.

ABSTRACT BODY:

Background: Systemic lupus erythematosus (SLE) is a complex disease possibly triggered by gene-environment interactions. Over 20% of SLE patients have symptoms before 18 years, making SLE the 2nd most common pediatric rheumatic disease. Data are scarce on how genetic variance contributes to disease risk. We have shown that most of the SLE-associated haplotypes encompass genomic regions enriched for epigenetic marks associated with enhancer function in neutrophils, and T/B cells, suggesting that genetic risk is exerted through altered gene regulation. Dysregulated gene expression has also been shown in SLE vascular endothelium.

Objective: We queried publically available genomic data from human umbilical vein endothelial cells (HUVEC) to determine whether genetic risk for SLE might impinge on vascular cell function.

Design/Methods: We used RegioneR (Bioconductor) to interrogate available data in ENCODE and Roadmap Epigenomics to identify epigenetic marks associated with enhancer or repressor function in HUVEC, and to determine whether these marks were enriched within the linkage disequilibrium (LD) blocks encompassing the 46 SNPs of interest. We identified typically associated domains (TADs) to look for enhancers and promoters in close proximity in 3-dimensional space within our LD blocks using Hi-C data in a web-based viewer, Juicebox.

Results: While HUVEC demonstrated enrichment for H3K4me1, H3K4me2, and H3K9ac within promoter

H3K36me3, and of transcription factor binding sites al... nomic background in genes found in regulation of the immune response, DNA binding, and cell cycle. We identified TADs in 16 genes in these regions, of which only 9 are expressed in HUVEC. Enrichment of repressive histone mark H3K36me3 was often seen overlapping TADs in the remaining 7 genes, all of which are involved in the pro-inflammatory response.

Conclusion(s): We were unable to find strong evidence that genetic risk for SLE is exerted through altered transcription regulation in HUVEC. Few of the genes in either the SLE risk haplotypes or associated TADs were expressed in HUVEC, consistent with enrichment for repressor-associated histone marks in these regions. This finding does not exclude the possibility that genetic variants may alter epigenetic features in these regions and lead to de-repression of pro-inflammatory genes.
